

FEATURES

- Dual operational amplifier**
- Voltage feedback**
- Wide supply range from 3 V to 24 V**
- Rail-to-rail output**
 - Output swing to within 0.5 V of supply rails
- High linear output current**
 - 310 mA peak into 32 Ω on ± 12 V supplies while maintaining -80 dBc SFDR
- Low noise**
 - 4.5 nV/ $\sqrt{\text{Hz}}$ voltage noise density at 100 kHz
 - 1.5 pA/ $\sqrt{\text{Hz}}$ current noise density at 100 kHz
- High speed**
 - 69 MHz bandwidth ($G = 1, -3$ dB)
 - 53 V/ μs slew rate ($R_{\text{LOAD}} = 25 \Omega$)

APPLICATIONS

- Twisted-pair line drivers
- Audio applications
- General-purpose ac applications

GENERAL DESCRIPTION

The AD8397 comprises two voltage feedback operational amplifiers capable of driving heavy loads with excellent linearity. The common-emitter, rail-to-rail output stage surpasses the output voltage capability of typical emitter-follower output stages and can swing to within 0.5 V of either rail while driving a 25 Ω load. The low distortion, high output current, and wide output dynamic range make the AD8397 ideal for applications that require a large signal swing into a heavy load.

Fabricated with Analog Devices, Inc., high speed extra fast complementary bipolar high voltage (XFCB-HV) process, the high bandwidth and fast slew rate of the AD8397 keep distortion to a minimum. The AD8397 is available in a standard 8-lead SOIC_N package and, for higher power dissipating applications, a thermally enhanced 8-lead SOIC_N_EP package. Both packages can operate from -40°C to $+85^\circ\text{C}$.

ABSOLUTE MAXIMUM RATINGS

Table 5.

Parameter	Rating
Supply Voltage	26.4 V
Power Dissipation ¹	See Figure 4
Storage Temperature Range	−65°C to +125°C
Operating Temperature Range	−40°C to +85°C
Lead Temperature (Soldering, 10 sec)	300°C
Junction Temperature	150°C

Stresses above those listed under Absolute Maximum Ratings may cause permanent damage to the device. This is a stress rating only; functional operation of the device at these or any other conditions above those indicated in the operational section of this specification is not implied. Exposure to absolute maximum rating conditions for extended periods may affect device reliability.

¹ Thermal resistance for standard JEDEC 4-layer board:
 8-lead SOIC_N: $\theta_{JA} = 157.6^{\circ}\text{C}/\text{W}$
 8-Lead SOIC_N_EP: $\theta_{JA} = 47.2^{\circ}\text{C}/\text{W}$

MAXIMUM POWER DISSIPATION

The maximum power that can be dissipated safely by the AD8397 is limited by the associated rise in junction temperature. The maximum safe junction temperature for plastic encapsulated devices is determined by the glass transition temperature of the plastic, approximately 150°C. Temporarily exceeding this limit may cause a shift in parametric performance due to a change in the stresses exerted on the die by the package.

Figure 4. Maximum Power Dissipation vs. Ambient Temperature

ESD CAUTION

ESD (electrostatic discharge) sensitive device. Charged devices and circuit boards can discharge without detection. Although this product features patented or proprietary protection circuitry, damage may occur on devices subjected to high energy ESD. Therefore, proper ESD precautions should be taken to avoid performance degradation or loss of functionality.

APPLICATIONS INFORMATION

The AD8397 is a voltage feedback operational amplifier that features an H-bridge input stage and common-emitter, rail-to-rail output stage. The AD8397 can operate from a wide supply range, ± 1.5 V to ± 12 V. When driving light loads, the rail-to-rail output is capable of swinging to within 0.2 V of either rail. The output can also deliver high linear output current when driving heavy loads, up to 310 mA into $32\ \Omega$ while maintaining -80 dBc SFDR. The AD8397 is fabricated on Analog Devices proprietary XFCB-HV.

POWER SUPPLY AND DECOUPLING

The AD8397 can be powered with a good quality, well-regulated, low noise supply from ± 1.5 V to ± 12 V. Pay careful attention to decoupling the power supply. Use high quality capacitors with low equivalent series resistance (ESR), such as multilayer ceramic capacitors (MLCCs), to minimize the supply voltage ripple and power dissipation. Locate a $0.1\ \mu\text{F}$ MLCC decoupling capacitor(s) no more than $1/8$ inch away from the power supply pin(s). A large tantalum $10\ \mu\text{F}$ to $47\ \mu\text{F}$ capacitor is recommended to provide good decoupling for lower frequency signals and to supply current for fast, large signal changes at the AD8397 outputs.

LAYOUT CONSIDERATIONS

As with all high speed applications, pay careful attention to printed circuit board (PCB) layout to prevent associated board parasitics from becoming problematic. The PCB should have a low impedance return path (or ground) to the supply. Removing the ground plane from all layers in the immediate area of the amplifier helps to reduce stray capacitances. The signal routing should be short and direct in order to minimize the parasitic inductance and capacitance associated with these traces. Locate termination resistors and loads as close as possible to their respective inputs and outputs. Keep input traces as far apart as possible from the output traces to minimize coupling (crosstalk) though the board.

When the AD8397 is configured as a differential driver, as in some line driving applications, provide a symmetrical layout to the extent possible in order to maximize balanced performance. When running differential signals over a long distance, the traces on the PCB should be close together or any differential wiring should be twisted together to minimize the area of the inductive loop that is formed. This reduces the radiated energy and makes the circuit less susceptible to RF interference. Adherence to stripline design techniques for long signal traces (greater than approximately 1 inch) is recommended.

UNITY-GAIN OUTPUT SWING

When operating the AD8397 in a unity-gain configuration, the output does not swing to the rails and is constrained by the H-bridge input. This can be seen by comparing the output overdrive recovery in Figure 7 and the input overdrive recovery in Figure 22. To avoid overdriving the input and to realize the full swing afforded by the rail-to-rail output stage, use the amplifier in a gain of two or greater.

Figure 22. Unity-Gain Input Overdrive Recovery

CAPACITIVE LOAD DRIVE

When driving capacitive loads, many high speed operational amplifiers exhibit peaking in their frequency response. In a gain-of-two circuit, Figure 23 shows that the AD8397 can drive capacitive loads up to 270 pF with only 3 dB of peaking. For amplifiers with more limited capacitive load drive, a small series resistor (R_s) is generally used between the amplifier output and the capacitive load in order to minimize peaking and ensure device stability. Figure 24 shows that the use of a 2.2 Ω series resistor can further extend the capacitive load drive of the AD8397 out to 470 pF, while keeping the frequency response peaking to within 3 dB.
