SMPS Series N-Channel IGBT with Anti-Parallel Hyperfast Diode

600 V

HGTG12N60A4D, HGTP12N60A4D, HGT1S12N60A4DS

The HGTG12N60A4D, HGTP12N60A4D and HGT1S12N60A4DS are MOS gated high voltage switching devices combining the best features of MOSFETs and bipolar transistors. These devices have the high input impedance of a MOSFET and the low on−state conduction loss of a bipolar transistor. The much lower on−state voltage drop varies only moderately between 25°C and 150°C. The IGBT used is the development type TA49335. The diode used in anti−parallel is the development type TA49371.

This IGBT is ideal for many high voltage switching applications operating at high frequencies where low conduction losses are essential. This device has been optimized for high frequency switch mode power supplies.
Formerly Developmental Type TA49337.

Features

- >100 kHz Operation 390 V, 12 A
- 200 kHz Operation 390 V, 9A
- 600 V Switching SOA Capability
- Typical Fall Time 70 ns at T_J = 125°C
- Low Conduction Loss
- Temperature Compensating Saber™ Model
- Related Literature

HGTG12N60A4D, HGTP12N60A4D, HGT1S12N60A4DS

ELECTRICAL CHARACTERISTICS (T$_J$ = 25°C unless otherwise specified) (continued)

Parameter	Symbol	Test Condition	Min	Typ	Max	Unit
Diode Forward Voltage	V$_{EC}$	I$_{EC}$ = 12 A	–	2.2	–	V
Diode Reverse Recovery Time	t$_{rr}$	I$_{EC}$ = 12 A, dI$_{EC}$/dt = 200 A/μs	–	30	–	ns
		I$_{EC}$ = 1 A, dI$_{EC}$/dt = 200 A/μs	–	18	–	ns
Thermal Resistance Junction To Case	R$_{\theta JC}$	IGBT	–	–	0.75	°C/W
		Diode	–	–	2.0	°C/W

Product parametric performance is indicated in the Electrical Characteristics for the listed test conditions, unless otherwise noted. Product performance may not be indicated by the Electrical Characteristics if operated under different conditions.

2. Turn−Off Energy Loss (E$_{OFF}$) is defined as the integral of the instantaneous power loss starting at the trailing edge of the input pulse and ending at the point where the collector current equals zero (I$_{CE}$ = 0 A). All devices were tested per JEDEC Standard No. 24−1 Method for Measurement of Power Device Turn−Off Switching Loss. This test method produces the true total Turn−Off Energy Loss.

3. Values for two Turn−On loss conditions are shown for the convenience of the circuit designer. E$_{ON1}$ is the turn−on loss of the IGBT only. E$_{ON2}$ is the turn−on loss when a typical diode is used in the test circuit and the diode is at the same T$_J$ as the IGBT. The diode type is specified in Figure 24.

HANDLING PRECAUTIONS FOR IGBTS

Insulated Gate Bipolar Transistors are susceptible to gate−insulation damage by the electrostatic discharge of energy through the devices. When handling these devices, care should be exercised to assure that the static charge built in the handler's body capacitance is not discharged through the device. With proper handling and application procedures, however, IGBTs are currently being extensively used in production by numerous equipment manufacturers in military, industrial and consumer applications, with virtually no damage problems due to electrostatic discharge. IGBTs can be handled safely if the following basic precautions are taken:

1. Prior to assembly into a circuit, all leads should be kept shorted together either by the use of metal shorting springs or by the insertion into conductive material such as "ECCOSORBD™ LD26" or equivalent.
2. When devices are removed by hand from their carriers, the hand being used should be grounded by any suitable means − for example, with a metallic wristband.
3. Tips of soldering irons should be grounded.
4. Devices should never be inserted into or removed from circuits with power on.
5. *Gate Voltage Rating* − Never exceed the gate−voltage rating of V_{GEM}. Exceeding the rated V_{GE} can result in permanent damage to the oxide layer in the gate region.
6. *Gate Termination* − The gates of these devices are essentially capacitors. Circuits that leave the gate open− circuited or floating should be avoided. These conditions can result in turn−on of the device due to voltage buildup on the input capacitor due to leakage currents or pickup.
7. *Gate Protection* − These devices do not have an internal monolithic Zener diode from gate to emitter. If gate protection is required an external Zener is recommended.

OPERATING FREQUENCY INFORMATION

Operating frequency information for a typical device (Figure 3) is presented as a guide for estimating device performance for a specific application. Other typical frequency vs collector current (I_{CE}) plots are possible using the information shown for a typical unit in Figures 5, 6, 7, 8, 9 and 11. The operating frequency plot (Figure 3) of a typical device shows f_{MAX1} or f_{MAX2}; whichever is smaller at each point. The information is based on measurements of a typical device and is bounded by the maximum rated junction temperature.

f_{MAX1} is defined by $f_{MAX1} = 0.05 / (t_{d(OFF)I} + t_{d(ON)I})$. Deadtime (the denominator) has been arbitrarily held to 10% of the on−state time for a 50% duty factor. Other definitions are possible. $t_{d(OFF)I}$ and $t_{d(ON)I}$ are defined in Figure 25. Device turn−off delay can establish an additional frequency limiting condition for an application other than T_{JM}. $t_{d(OFF)I}$ is important when controlling output ripple under a lightly loaded condition.

f_{MAX2} is defined by $f_{MAX2} = (P_D − P_C) / (E_{OFF} + E_{ON2})$. The allowable dissipation (P_D) is defined by $P_D = (T_{JM} − T_C) / R_{\theta JC}$. The sum of device switching and conduction losses must not exceed P_D. A 50% duty factor was used (Figure 3) and the conduction losses (P_C) are approximated by $P_C = (V_{CE} \times I_{CE}) / 2$.

E_{ON2} and E_{OFF} are defined in the switching waveforms shown in Figure 25. E_{ON2} is the integral of the instantaneous power loss ($I_{CE} \times V_{CE}$) during turn−on and E_{OFF} is the integral of the instantaneous power loss ($I_{CE} \times V_{CE}$) during turn−off. All tail losses are included in the calculation for E_{OFF}; i.e., the collector current equals zero ($I_{CE} = 0$).
