STA323W

## 2.1 high efficiency digital audio system

Features

- Wide supply voltage range (10-36 V)
- 3 x power output configurations
  - 2 x 10 W + 1x 20 W
  - 2 x 20 W
  - 1 x 40 W
- Thermal protection
- Under voltage protection
- Short circuit protection
- Power SO-36 Slug Down package
- 2.1 channels of 24-bit DDX®
- 100 dB SNR and dynamic range
- 32 kHz to 192 kHz input sample rates
- Digital gain/attenuation +48 dB to -80 dB in 0.5 dB steps
- 4 x 28-bit user programmable biquads (EQ) per channel
- I²C control
- 2-channel I²S input data interface
- Individual channel and master gain/attenuation
- Individual channel and master soft and hard mute
- Individual channel volume and EQ bypass
- DDX® POP free operation
- Bass/treble tone control
- Dual independent programmable limiters/compressors
- Automodes™
  - 32 preset EQ curves
  - 15 preset crossover settings
  - Auto volume controlled loudness
  - 3 preset volume curves
  - 2 preset anti-clipping modes
  - Preset nighttime listening mode
  - Preset TV AGC

- Input and output channel mapping
- AM noise reduction and PWM frequency shifting modes
- Soft volume update and muting
- Auto zero detect and invalid input detect muting selectable DDX® ternary or binary PWM output + variable PWM speeds
- Selectable de-emphasis
- Post-EQ user programmable mix with default 2.1 bass management settings
- Variable max power correction for lower full-power THD
- 4 output routing configurations
- Selectable clock input ratio
- 96 kHz internal processing sample rate, 24 to 28-bit precision
  - Video application: 576 fs input mode supporting

Order codes

1 Description

The STA323W is a single-chip audio system comprising digital audio processing, digital amplifier control and a DDX-power output stage. The STA323W uses all-digital amplification to provide high-power, high-quality and high-efficiency.

The STA323W power section consists of four independent half-bridges. These can be configured, by digital control, to operate in the following modes.

● Two channels, provided by two half-bridges, and a single full-bridge giving up to 2 x 10 W + 1 x 20 W of power output.

● Two channels, provided by two full-bridges, giving up to 2 x 20 W of power.

● A single, parallel, full-bridge channel capable of high-current operation and giving 1 x 40W output.

The STA323W also provides a full set of digital processing features. These includes up to four programmable 28-bit biquads (EQ) per channel, and bass and treble tone control. Automodes™ enable a time-to-market advantage by substantially reducing the amount of software development needed for specific functions. These includes auto volume loudness, preset volume curves and preset EQ settings. New advanced AM radio interference reduction modes are also provided.

The serial audio data input interface accepts all existing formats, including the I²S.

Three channels of DDX® processing are provided. This high quality conversion from PCM audio to DDX's patented tri-state PWM switching waveform provides over 100 dB SNR and dynamic range.

1.1 Block diagram and configurations

Figure 1. Block diagram
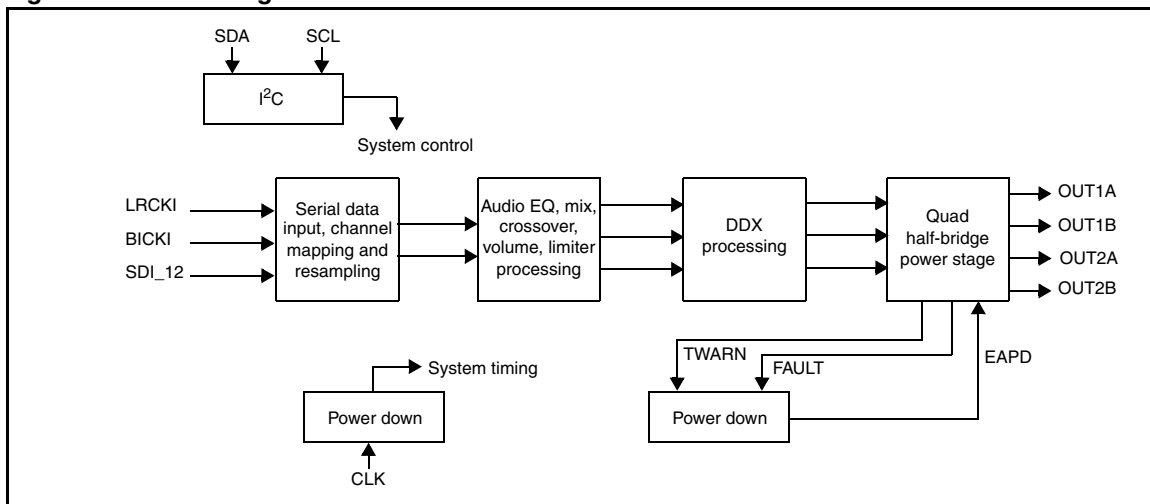

Figure 2. Channel signal flow diagram through the digital core
1.2 EQ processing

Two channels of input data (re-sampled if necessary) at 96 kHz are provided to the EQ processing block. In these blocks, up to four user-defined Biquads can be applied to each of the two channels.

Pre-scaling, DC-blocking high-pass, de-emphasis, bass, and tone control filters can also be implemented by means of configuration parameter settings.

The entire EQ block can be bypassed for all channels simultaneously by setting the DSPB bit to '1'. The CxEQBP bits can also be used to bypass the EQ functionality on a per channel basis. *Figure 3* shows the internal signal flow through the EQ block.

Symbol	Parameter	Test condition	Min.	Typ.	Max.	Unit
treset	Reset hold time (pin 22)	Active low rest	100			nSec
VCO	VCO free run frequency	No clock applied to XTI	18	28		

Figure 11.   Test circuit
3.1   Power supply and control sequencing

Figure 12 shows the recommended power-up and power-down sequencing. The "time zero" reference point is taken where V_{CC} crosses the under voltage lockout threshold.

Figure 12.   Recommended power up and power down sequence
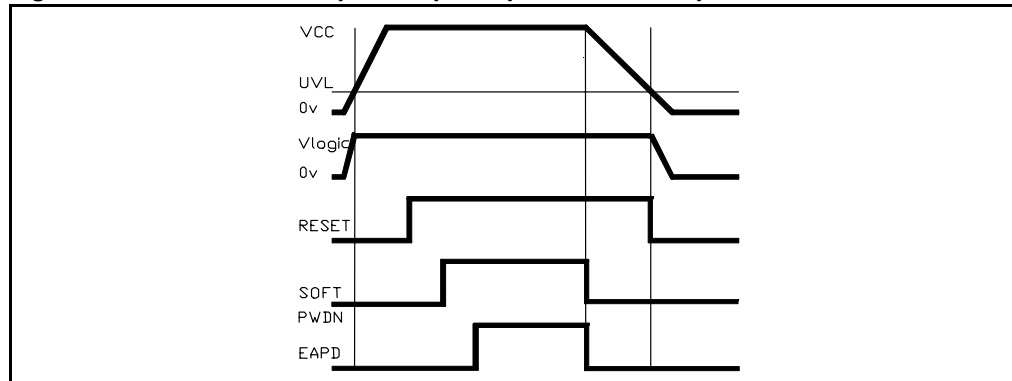

4   Electrical characteristics curves

4.1   Output power against supply voltage

Figure 13.   Stereo mode - output power against supply voltage, THD+N = 10%
Figure 13 shows the full-scale output power (0dB FS digital input with unity amplifier gain) as a function of power supply voltage for 4, 6, and 8 Ω loads in either DDX® mode or binary full bridge mode. Output power is constrained for higher impedance loads by the maximum voltage limit of the STA323W and by the over-current protection limit for lower impedance loads. The minimum threshold for the over-current protection circuit of the STA323W is 4 A (at 25 °C) but the typical threshold is 6 A for the device. The solid curves shows the typical output power capability of the device. The dotted curves shows the output power capability constrained to the minimum current specification of the STA323W. The output power curves assume proper thermal management of the power device's internal dissipation.

Figure 14.   Output power vs. supply for stereo bridge (THD+N=1%)
Figure 14 shows the mono mode output power as a function of power supply voltages for loads of 2, 3, and Ω Ohms. The same current limits as those given for *Figure 13* apply, except output current is 8 A minimum, with 12 A typical in the mono-bridge configuration. The solid curves show typical performance and dashed curves depict the minimum current limit. The output power curves assume proper thermal management of the power device's internal dissipation.

Figure 15.   Half-bridge binary mode output power vs. supply (THD+N=10%).
Curves taken at f = 1 kHz and using a 330µF blocking capacitor
Figure 15 shows the output power as a function of power supply voltages for loads of 4, 6, and 8 Ω when the STA323W is operated in a half-bridge binary mode. The solid curves depict typical performance. Minimum current limit is not reached for these combinations of voltage and load impedance. The output power curves assume proper thermal management of the power device's internal dissipation.

Figure 16. Half bridge binary mode output power vs. supply voltage (THD+N=1%). Curves taken at 1 kHz and using a 330µF blocking capacitor

5   Pin descriptions

OUT1A, 1B, 2A and 2B (Pins 16, 10, 9 and 3)

The half-bridge PWM outputs 1A, 1B, 2A and 2B provide the inputs signals to the speakers.

OUT1A, 1B, 2A and 2B (Pins 16, 10, 9 and 3)

Driving RESET low sets all outputs low and returns all register settings to their defaults. The reset is asynchronous to the internal clock.

OUT1A, 1B, 2A and 2B (Pins 16, 10, 9 and 3)

The SDA (I^{2}C Data) and SCL (I^{2}C Clock) pins operate according to the I^{2}C specification (See *Chapter 6 on page 30*.) Fast-mode (400 kB/sec.) I^{2}C communication is supported.

OUT1A, 1B, 2A and 2B (Pins 16, 10, 9 and 3)

The phase locked loop power is applied here. This +3.3V supply must be well bypassed and filtered for noise immunity. The audio performance of the device is critically dependent upon the PLL circuit.

OUT1A, 1B, 2A and 2B (Pins 16, 10, 9 and 3)

This is the master clock input required for the operation of the digital core. The master clock must be an integer multiple of the LR clock frequency. Typically, the master clock frequency is 12.288 MHz (256 * Fs) for a 48kHz sample rate, which is the default at power-up. Do not over-clock the device (use a frequency higher than that recommended for the system clock) otherwise it may not operate correctly or be able to communicate.

OUT1A, 1B, 2A and 2B (Pins 16, 10, 9 and 3)

The PLL filter connects to external filter components for PLL loop compensation. Refer to the schematic diagram *Figure 9: Power schematic for 1 mono parallel channel on page 11* for the recommended circuit.

OUT1A, 1B, 2A and 2B (Pins 16, 10, 9 and 3)

The serial or bit clock input is for framing each data bit. The bit clock frequency, using I^{2}S serial format, is typically 64 * Fs .

OUT1A, 1B, 2A and 2B (Pins 16, 10, 9 and 3)

PCM audio information enters the device here. Six format choices are available including I^{2}S, left- or right-justified, LSB or MSB first, with word widths of 16, 18, 20 and 24 bits.

OUT1A, 1B, 2A and 2B (Pins 16, 10, 9 and 3)

The left/right clock input is for data word framing. The clock frequency is at the input sample rate Fs.

6   STA323W I^{2}C bus specification

The STA323W supports the I^{2}C fast mode (400 Kbit/s) protocol. This protocol defines any device that sends data on to the bus as a transmitter and any device that reads the data as a receiver. The device that controls the data transfer is known as the master and the other as the slave. The master always starts the transfer and provides the serial clock for synchronization. The STA323W is always a slave device in all of its communications.

6.1   Communication protocol

6.1.1   Data transition or change

Data changes on the SDA line must only occur when the SCL clock is low. SDA transition while the clock is high is used to identify a START or STOP condition.

6.1.2   Start condition

START is identified by a high to low transition of the data bus SDA signal while the clock signal SCL is stable in the high state. A START condition must precede any command for data transfer.

6.1.3   Stop condition

STOP is identified by a low to high transition of the data bus SDA signal while the clock signal SCL is stable in the high state. A STOP condition terminates communication between STA323W and the bus master.

6.1.4   Data input

During the data input the STA323W samples the SDA signal on the rising edge of clock SCL. For correct device operation the SDA signal must be stable during the rising edge of the clock and the data can change only when the SCL line is low.

6.2   Device addressing

To start communication between the master and the STA323W, the master must initiate with a START condition. Following this, the master sends 8 bits (MSB first) on the SDA line corresponding to the device select address and read or write mode.

The 7 most significant bits are the device address identifiers, corresponding to the I^{2}C bus definition. In the STA323W the I^{2}C interface uses a device address of 0x34 or 0011010x.

The 8th bit (LSB) identifies read or write operation, RW. This bit is set to 1 in read mode and 0 for write mode. After a START condition the STA323W identifies the device address on the bus. If a match is found, it acknowledges the identification on the SDA bus during the 9th bit time. The byte following the device identification byte is the internal space address.

6.3   Write operation

Following the START condition the master sends a device select code with the RW bit set to 0. The STA323W acknowledges this and then the master writes the internal address byte.

After receiving the internal byte address the STA323W again responds with an acknowledgement.

6.3.1   Byte write

In the byte write mode the master sends one data byte. This is acknowledged by the STA323W. The master then terminates the transfer by generating a STOP condition.

6.3.2   Multi-byte write

The multi-byte write modes can start from any internal address. Sequential data bytes are written to sequential addresses within the STA323W.

The master generates a STOP condition to terminate the transfer.

6.4   Read operation

6.4.1   Current address byte read

Following the START condition the master sends a device select code with the RW bit set to 1. The STA323W acknowledges this and then responds by sending one byte of data. The master then terminates the transfer by generating a STOP condition.

Current address multi-byte read

The multi-byte read modes can start from any internal address. Sequential data bytes are read from sequential addresses within the STA323W. The master acknowledges each data byte read and then generates a STOP condition to terminate the transfer.

6.4.2   Random address byte read

Following the START condition the master sends a device select code with the RW bit set to 0. The STA323W acknowledges this and then the master writes the internal address byte. After receiving, the internal byte address the STA323W again responds with an acknowledgement. The master then initiates another START condition and sends the device select code with the RW bit set to 1. The STA323W acknowledges this and then responds by sending one byte of data. The master then terminates the transfer by generating a STOP condition.

Random address multi-byte read

The multi-byte read modes can start from any internal address. Sequential data bytes are then read from sequential addresses within the STA323W. The master acknowledges each data byte read and then generates a STOP condition to terminate the transfer.

7.1 Configuration register A (address 0x00)

D7	D6	D5	D4	D3	D2	D1	D0
FDRB	TWAB	TWRB	IR1	IR0	MCS2	MCS1	MCS0
0	1	1	0	0	0	1	1

7.1.1 Master clock select

Table 13. Master clock select

Bit	R/W	RST	Name	Description
0	R/W	1	MCS0	Master clock select: selects the ratio between the input I^2S sample frequency and the input clock.
1	R/W	1	MCS1	
2	R/W	0	MCS2	

The STA323W supports sample rates of 32 kHz, 44.1 kHz, 48 khz, 88.2 kHz, and 96 kHz. Therefore the internal clock is:

● 32.768 MHz for 32 kHz

● 45.1584 MHz for 44.1 khz, 88.2 kHz, and 176.4 kHz

● 49.152 MHz for 48 kHz, 96 kHz, and 192 kHz

The external clock frequency provided to the XTI pin must be a multiple of the input sample frequency (fs). The correlation between the input clock and the input sample rate is determined by the status of the MCSx bits and the IR (Input Rate) register bits. The MCSx bits determine the PLL factor generating the internal clock and the IR bit determines the oversampling ratio used internally.

Table 14.   IR and MCS settings for input sample rate and clock rate

Input sample rate fs (kHz)	IR	MCS(2..0)					
		000	**001**	**010**	**011**	**100**	**101**
32, 44.1, 48	00	768fs	512fs	384fs	256fs	128fs	576fs
88.2, 96	01	384fs	256fs	192fs	128fs	64fs	x
176.4, 192	1X	384fs	256fs	192fs	128fs	64fs	x

7.1.2   Interpolation ratio select

Table 15.   Interpolation ratio select

Bit	R/W	RST	Name	Description
4...3	R/W	00	IR (1...0)	Selects internal interpolation ratio based on input I^2S sample frequency

The STA323W has variable interpolation (re-sampling) settings such that internal processing and DDX output rates remain consistent. The first processing block interpolates by either 2 times or 1 time (pass-through) or provides a down-sample by a factor of 2.

The IR bits determine the re-sampling ratio of this interpolation.

Table 16.   IR bit settings as a function of input sample rate

Input sample rate Fs (kHz)	IR (1, 0)	1st stage interpolation ratio
32	00	2 times over-sampling
44.1	00	2 times over-sampling
48	00	2 times over-sampling
88.2	01	Pass-Through
96	01	Pass-Through
176.4	10	Down-sampling by 2
192	10	Down-sampling by 2

7.1.3 Thermal warning recovery bypass

Table 17. Thermal warning recovery bypass

Bit	R/W	RST	Name	Description
5	R/W	1	TWRB	0: Thermal warning Recovery enabled 1: Thermal warning Recovery disabled

If the thermal warning adjustment is enabled (TWAB=0), then the thermal warning recovery determines if the adjustment is removed when thermal warning is negative. If TWRB=0 and TWAB=0, then, when a thermal warning disappears, the gain adjustment determined by the thermal warning post-scale (default = -3 dB) is removed and the gain is applied to the system. If TWRB=1 and TWAB=0, then when a thermal warning disappears, the thermal warning post-scale gain adjustment remains until TWRB is changed to zero or the device is reset.

7.1.4 Thermal warning adjustment bypass

Table 18. Thermal warning adjustment bypass

Bit	R/W	RST	Name	Description
6	R/W	1	TWAB	0: thermal warning adjustment enabled 1: thermal warning adjustment disabled

The STA323W on-chip power output block provides feedback to the digital controller by the power control block inputs. The TWARN input is used to indicate a thermal warning condition. When TWARN is active (set to 0 for a period greater than 400 ms) the power control block forces an adjustment to the modulation limit in an attempt to eliminate the thermal warning condition. Once the thermal warning volume adjustment is applied, whether the gain is reapplied when TWARN is inactive, depends on the TWRB bit.

7.1.5 Fault detect recovery bypass

Table 19. Fault detect recovery bypass

Bit	R/W	RST	Name	Description
7	R/W	0	FDRB	0: fault detector recovery enabled 1: fault detector recovery disabled

The DDX power block provides feedback to the digital controller using inputs to the power control block. The FAULT input is used to indicate a fault condition (either over-current or thermal). When FAULT is active (set to 0), the power control block attempts a recovery from the fault by activating the tri-state output (setting it to 0 which directs the power output block to begin recovery). It holds it at 0 for period of time in the range of 0.1 ms to 1 second as defined by the Fault-Detect Recovery Constant register (FDRC registers 29-2Ah), then toggles it back to 1. This sequence is repeated as long as the fault indication exists. This feature is enabled by default but can be bypassed by setting the FDRB control bit to 1.

7.2 Configuration register B (address 0x01)

D7	D6	D5	D4	D3	D2	D1	D0
C1IM	C1IM	DSCKE	SAIFB	SAI3	SAI2	SAI1	SAI0
1	0	0	0	0	0	0	0

7.2.1 Serial audio input interface format

Table 20.   Serial audio input interface format

Bit	R/W	RST	Name	Description
3…0	R/W	0000	SAI (3...0)	Determines the interface format of the input serial digital audio interface.

7.3 Serial data interface

The STA323W serial audio input interfaces with standard digital audio components and accepts several different serial data formats. The STA323W always acts as a slave when receiving audio input from standard digital audio components. Serial data for two channels is provided using 3 input pins: left/right clock LRCKI (pin 33), serial clock BICKI (pin 31), and serial data 1 and 2 SDI12 (pin 32).

The SAI register (configuration register B - 0x01, bits D3-D0) and the SAIFB register (configuration register B - 0x01, bit D4) are used to specify the serial data format. The default serial data format is I^2S, MSB first. The formats available are shown in *Figure 48* and in *Table 21*, *Table 22*, and *Table 22*.

Figure 48.   General serial input and output formats
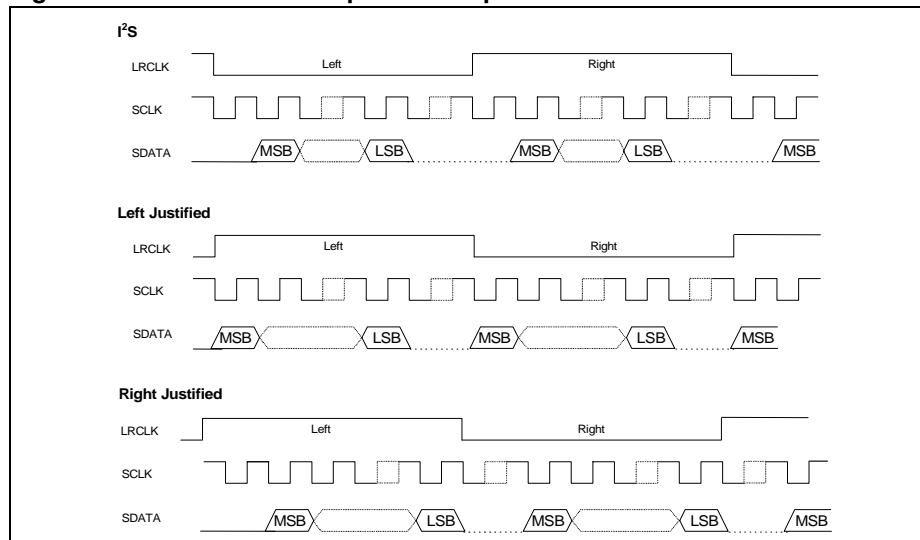

For example, SAI=1110 and SAIFB=1 specifies right justified 16-bit data, LSB first.

Table 22. lists the serial audio input formats supported by STA323W when
BICKI = 32 * fs, 48 * fs or 64 * fs, where the sampling rate fs = 32, 44.1, 48, 88.2, 96, 176.4
or 192 kHz.

Table 21. First bit selection table

SAIFB	Format
0	MSB first
1	LSB first

Note: *Serial input and output formats are specified distinctly.*

Table 22. Supported serial audio input formats

BICKI	SAI (3...0)	SAIFB	Interface format
32fs	1100	X	I^2S 15-bit data
	1110	X	Left/right-justified 16-bit data
48fs	0100	X	I^2S 23-bit data
	0100	X	I^2S 20-bit data
	1000	X	I^2S 18-bit data
	0100	0	MSB first I^2S 16-bit data
	1100	1	LSB first I^2S 16-bit data
	0001	X	Left-justified 24-bit data
	0101	X	Left-justified 20-bit data
	1001	X	Left-justified 18-bit data
	1101	X	Left-justified 16-bit data
	0010	X	Right-justified 24-bit data
	0110	X	Right-justified 20-bit data
	1010	X	Right-justified 18-bit data
	1110	X	Right-justified 16-bit data
64fs	0000	X	I^2S 24-bit data
	0100	X	I^2S 20-bit data
	1000	X	I^2S 18-bit data
	0000	0	MSB first I^2S 16-bit data
	1100	1	LSB first I^2S 16-bit data
	0001	X	Left-justified 24-bit data
	0101	X	Left-justified 20-bit data
	1001	X	Left-justified 18-bit data
	1101	X	Left-justified 16-bit data
	0010	X	Right-justified 24-bit data
	0110	X	Right-justified 20-bit data

Table 22.   Supported serial audio input formats (continued)

BICKI	SAI (3...0)	SAIFB	Interface format
	1010	X	Right-justified 18-bit data
	1110	X	Right-justified 16-bit data

Table 23.   Serial input data timing characteristics (Fs = 32 to 192 kHz)

Signal	Frequency
BICKI frequency (slave mode)	12.5 MHz max.
BICKI pulse width high (T1) (slave mode)	40 ns min.
BICKI active to LRCKI edge delay (T2)	20 ns min.
BICKI active to LRCKI edge delay (T3)	20 ns min.
SDI valid to BICKI active setup (T4)	20 ns min.
BICKI active to SDI hold time (T5)	20 ns min.

Figure 49.   Serial input and data timing
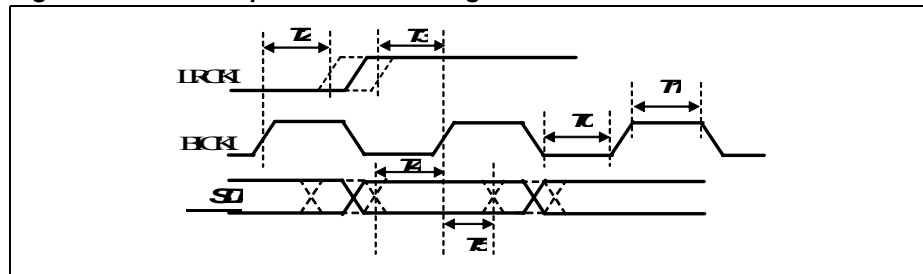

7.3.1   Delay serial clock enable

Table 24.   Delay serial clock enable

Bit	R/W	RST	Name	Description
5	R/W	0	DSCKE	0: no serial clock delay 1: serial clock delay by 1 core clock cycle to tolerate anomalies in some I^2S master devices

Table 25.   Channel input mapping

Bit	R/W	RST	Name	Description
6	R/W	0	C1IM	0: processing channel 1 receives left I^2S input 1: processing channel 1 receives right I^2S input
7	R/W	1	C2IM	0: processing channel 2 receives left I^2S input 1: processing channel 2 receives right I^2S input

Each channel received from the I^2S can be mapped to any internal processing channel via the channel input mapping registers. This allows processing flexibility. The default settings of these registers map each I^2S input channel to its corresponding processing channel.

7.4 Configuration register C (address 0x02)

D7	D6	D5	D4	D3	D2	D1	D0
	CSZ4	CSZ3	CSZ2	CSZ1	CSZ0	OM1	OM0
	1	0	0	0	0	1	0

7.4.1 DDX® power output mode

Table 26. DDX® power output mode

Bit	R/W	RST	Name	Description
1...0	R/W	10	OM (1...0)	Selects configuration of DDX® output.

The DDX® power output mode selects how the DDX® output timing is configured. Different power devices can use different output modes. The recommended use is OM = 10. When OM=11 the CSZ bits determine the size of the DDX® compensating pulse.

Table 27. DDX® output modes

OM (1,0)	Output stage – mode
00	Not used
01	Not used
10	Recommended
11	Variable compensation

7.4.2 DDX® variable compensating pulse size

The DDX® variable compensating pulse size is intended to adapt to different power stage ICs. Contact ST for support when using this function.

Table 28. DDX® compensating pulse

CSZ (4…0)	Compensating pulse size
00000	0 clock period compensating pulse size
00001	1 clock period compensating pulse size
…	…
10000	16 clock period compensating pulse size
…	…
11111	31 clock period compensating pulse size

7.5 Configuration register D (address 0x03)

D7	D6	D5	D4	D3	D2	D1	D0
MME	ZDE	DRC	BQL	PSL	DSPB	DEMP	HPB
0	0	0	0	0	0	0	0

7.5.1 High-pass filter bypass

Table 29.   High-pass filter bypass

Bit	R/W	RST	Name	Description
0	R/W	0	HPB	0: AC coupling high pass filter enabled 1: AC coupling high pass filter enabled

The STA323W features an internal digital high-pass filter for DC blocking. The purpose of this filter is to prevent DC signals from passing through a DDX® amplifier. DC signals can cause speaker damage.

7.5.2 De-emphasis

Table 30.   De-emphasis

Bit	R/W	RST	Name	Description
1	R/W	0	DEMP	0: no de-emphasis 1: de-emphasis

By setting this bit to 1, de-emphasis is implemented on all channels. DSPB (DSP Bypass, Bit D2, CFA) bit must be set to 0 for de-emphasis to function.

7.5.3 DSP bypass

Table 31.   DSP bypass

Bit	R/W	RST	Name	Description
2	R/W	0	DSPB	0: normal operation 1: bypass of EQ and mixing functionality

Setting the DSPB bit bypasses all the EQ and mixing functionality of the STA323W core.

7.5.4 Post-scale link

Table 32.   Post-scale link

Bit	R/W	RST	Name	Description
3	R/W	0	PSL	0: each channel uses individual post-scale value 1: each channel uses channel 1 post-scale value

Post-scale functionality is an attenuation placed after the volume control and directly before the conversion to PWM. Post-scale can also be used to limit the maximum modulation index and therefore the peak current. Setting 1, in the PSL register, causes the value stored in Channel 1 post-scale to be used for all three internal channels.

7.5.5 Biquad coefficient link

Table 33. Biquad coefficient link

Bit	R/W	RST	Name	Description
4	R/W	0	BQL	0: each channel uses coefficient values 1: each channel uses channel 1 coefficient values

For ease of use, all channels can use the biquad coefficients loaded into the channel 1 coefficient RAM space by setting the BQL bit to 1. Therefore, any EQ updates only have to be performed once.

7.5.6 Dynamic range compression/anti-clipping bit

Table 34. Dynamic range compression/anti-clipping bit

Bit	R/W	RST	Name	Description
5	R/W	0	DRC	0: limiters act in anti-clipping mode 1: limiters act in dynamic range compression mode

Both limiters can be used in one of two ways: anti-clipping or dynamic range compression. When used in anti-clipping mode the limiter threshold values are constant and dependent on the limiter settings. In dynamic range compression mode the limiter threshold values vary with the volume settings allowing a nighttime listening mode that provides a reduction in the dynamic range regardless of the volume level.

7.5.7 Zero-detect mute enable

Table 35. Zero-detect mute enable

Bit	R/W	RST	Name	Description
6	R/W	1	ZDE	Setting of 1 enables the automatic zero-detect mute

Setting the ZDE bit enables the zero-detect automatic mute. When ZDE=1, the zero-detect circuit looks at the input data to each processing channel after the channel-mapping block. If any channel receives 2048 consecutive zero value samples (regardless of fs) then that individual channel is muted if this function is enabled.

7.6 Configuration register E (address 0x04)

D7	D6	D5	D4	D3	D2	D1	D0
SVE	ZCE	RES	PWMS	AME	RES	MPC	MPCV
0	0	0	0	0	0	0	0

7.6.1 Max power correction variable

Table 36.   Max power correction variable

Bit	R/W	RST	Name	Description
0	R/W	0	MPCV	0: use standard MPC coefficient 1: use MPCC bits for MPC coefficient

By enabling MPC and setting MPCV = 1, the max power correction becomes variable. By adjusting the MPCC registers (address 0x27-0x28) it is possible to adjust the THD at maximum unclipped power to a lower value for a particular application.

7.6.2 Max power correction

Table 37.   Max power correction

Bit	R/W	RST	Name	Description
7	R/W	1	MPC	0: MPC disabled 1: MPC enabled

Setting the MPC bit corrects the power device at high power. This mode lowers the THD+N of the full DDX® system at, and slightly below, maximum power output.

7.6.3 AM mode enable

Table 38.   AM mode enable

Bit	R/W	RST	Name	Description
3	R/W	0	AME	0: normal DDX® operation 1: AM reduction mode DDX® operation

The STA323W features a DDX® processing mode that minimizes the amount of noise generated in the frequency range of AM radio. This mode is intended for use when DDX® is operating in a device with an active AM tuner. The SNR of the DDX® processing is reduced to ~83 dB in this mode, which is still greater than the SNR of AM radio.

7.6.4 PWM speed mode

Table 39.   PWM speed mode

Bit	R/W	RST	Name	Description
4	R/W	0	PWMS	Normal or odd

Table 40.   PWM output speed selections

PWMS (1...0)	PWM output speed
0	Normal speed (384kHz) all channels
1	Odd speed (341.3kHz) all channels

7.6.5 Zero-crossing volume enable

Table 41.   Zero-crossing volume enable

Bit	R/W	RST	Name	Description
6	R/W	1	ZCE	1: volume adjustments will only occur at digital zero-crossings 0: volume adjustments will occur immediately

The ZCE bit enables zero-crossing volume adjustments. When volume is adjusted on digital zero-crossings no clicks are audible.

7.6.6 Soft volume update enable

Table 42.   Soft volume update enable

Bit	R/W	RST	Name	Description
7	R/W	1	SVE	1: volume adjustments will use soft volume 0: volume adjustments will occur immediately

The STA323W includes a soft volume algorithm that steps through the intermediate volume values at a predetermined rate when a volume change occurs. By setting SVE=0 this can be bypassed and volume changes will jump from the old to the new value directly. This feature is available only if individual channel volume bypass bit is set to 0.

7.7 Configuration register F (address 0x05)

D7	D6	D5	D4	D3	D2	D1	D0
EAPD	PWDN	ECLE	RES	BCLE	IDE	OCFG1	OCFG0
0	1	0	1	1	1	1	0

7.7.1 Output configuration selection

Table 43. Output configuration selection

Bit	R/W	RST	Name	Description
1…0	R/W	00	OCFG (1…0)	00 – 2-channel (full-bridge) power, 1-channel DDX is default

Table 44. Output configuration selections

OCFG (1...0)	Output power configuration
00	2 channel (full-bridge) power, 1 channel DDX: 1A/1B ◊ 1A/1B 2A/2B ◊ 2A/2B
01	2(half-bridge).1(full-bridge) on-board power: 1A ◊ 1A Binary 2A ◊ 1B Binary 3A/3B ◊ 2A/2B Binary
10	Reserved
11	1 channel mono-parallel: 3A ◊ 1A/1B 3B ◊ 2A/2B

Table 45. Invalid input detect mute enable

Bit	R/W	RST	Name	Description
2	R/W	1	IDE	0: disabled 1: enabled

Setting the IDE bit enables this function, which looks at the input I^2S data and clocking and automatically mutes all outputs if the signals are invalid.

Table 46. Binary clock loss detection enable

Bit	R/W	RST	Name	Description
5	R/W	1	BCLE	0: disabled 1: enabled

Detects loss of input MCLK in binary mode and outputs 50% duty cycle to prevent audible noise when input clocking is lost.

Table 47.   Auto-EAPD on clock loss enable

Bit	R/W	RST	Name	Description
7	R/W	0	ECLE	0: disabled 1: enabled

When ECLE is active, it issues a power device power down signal (EAPD) on clock loss detection.

Table 48.   External amplifier power down

Bit	R/W	RST	Name	Description
7	R/W	0	EAPD	0: external power stage power down active 1: normal operation

EAPD is used to actively power down a connected DDX® power device. This register has to be written to 1 at start-up to enable the DDX® power device for normal operation.

7.8   Volume control

7.8.1   Master controls

0	1	1	0	0	0	0	0

7.8.3   Volume description

The volume structure of the STA323W consists of individual volume registers for each of the three channels and a master volume register, and individual channel volume trim registers. The channel volume settings are normally used to set the maximum allowable digital gain and to hard-set gain differences between certain channels. These values are normally set at the initialization of the IC and not changed. The individual channel volumes are adjustable in 0.5 dB steps from +48 dB to -80 dB. The master volume control is normally mapped to the master volume of the system. The values of these two settings are summed to find the actual gain or volume value for any given channel.

When set to 1, the Master Mute will mute all channels, whereas the individual channel mutes (CxM) will mute only that channel. Both the Master Mute and the Channel Mutes provide a "soft mute" with the volume ramping down to mute in 4096 samples from the maximum volume setting at the internal processing rate (~96 kHz). A "hard mute" can be obtained by setting a value of all 1's (FFh) in any channel volume register or the master volume register. When volume offsets are provided, via the master volume register, any channel whose total volume is less than –100dB is muted.

All changes in volume take place at zero-crossings when ZCE = 1 (configuration register E) on a per channel basis as this creates the smoothest possible volume transitions. When ZCE=0, volume updates occur immediately.

The STA323W also features a soft-volume update function. When SVE = 1 (in configuration register E) the volume ramps between intermediate values when the value is updated, This feature can be disabled by setting SVE = 0.

Each channel also contains an individual channel volume bypass. If a particular channel has volume bypassed via the CxVBP = 1 register then only the channel volume setting for that particular channel affects the volume setting, the master volume setting does not affect that channel. Also, master soft-mute does not affect the channel if CxVBP = 1.

Each channel also contains a channel mute. If CxM = 1 a soft mute is performed on that channel.

Table 49. **Master volume offset as a function of MV (7..0)**

MV (7..0)	Volume offset from channel value
00000000 (00h)	0dB
00000001 (01h)	-0.5dB
00000010 (02h)	-1dB

000	0.535 MHz – 0.720 MHz	0.535 MHz – 0.670 MHz
001	0.721 MHz – 0.900 MHz	0.671 MHz – 0.800 MHz
010	0.901 MHz – 1.100 MHz	0.801 MHz – 1.000 MHz
011	1.101 MHz – 1.300 MHz	1.001 MHz – 1.180 MHz

Table 56. Auto mode AM switching frequency selection (continued)

AMAM (2..0)	48 kHz/96 kHz input Fs	44.1 kHz/88.2 kHz input Fs
100	1.301 MHz – 1.480 MHz	1.181 MHz – 1.340 MHz
101	1.481 MHz – 1.600 MHz	1.341 MHz – 1.500 MHz
110	1.601 MHz – 1.700 MHz	1.501 MHz – 1.700 MHz

When DDX® is used with an AM radio tuner, it is recommended to use the AMAM bits to automatically adjust the output PWM switching rate so that it depends on the specific radio frequency that the tuner is receiving. The values used in AMAM are also dependent upon the sample rate that is determined by the ADC used.

Table 57. Automode crossover setting

Bit	R/W	RST	Name	Description

C3OM1	C3OM0	C3LS1	C3LS0	C3BO	C3VBP		
0	0	0	0	0	0		

EQ control can be bypassed on a per channel basis. If EQ control is bypassed on a given channel the prescale and all 9 filters (high-pass, biquads, de-emphasis, bass management cross-over, bass, treble in any combination) are bypassed for that channel.

CxEQBP:

- 0: perform EQ on channel X (normal operation)
- 1: bypass EQ on channel X

Tone control (bass and treble) can be bypassed on a per channel basis. If tone control is bypassed on a given channel the two filters that tone control utilizes are bypassed.

CxTCB:

- 0: perform tone control on channel x – (default operation)
- 1: bypass tone control on channel x

Each channel can be configured to output either the patented DDX PWM data or standard binary PWM encoded data. By setting the CxBO bit to '1', each channel can be individually set to binary operation mode.

It is also possible to map each channel independently to either of the two limiters available within the STA323W. In the default mode the channels are not mapped to a limiter.

Table 60. Channel Limiter Mapping Selection

CxLS (1,0)	Channel limiter mapping
00	Channel has limiting disabled
01	Channel is mapped to limiter #1
10	Channel is mapped to limiter #2

Each PWM output channel can receive data from any channel output of the volume block. Which channel a particular PWM output receives depends on the CxOM register bits for that channel.

7.12.5 Dynamics control description

The STA323W includes two independent limiter blocks. The purpose of the limiters is to automatically reduce the dynamic range of a recording to prevent the outputs from clipping in anti-clipping mode, or to actively reduce the dynamic range for a better listening environment (such as a night-time listening mode, which is often needed for DVDs.) The two modes are selected via the DRC bit in Configuration Register D, bit 5 address 0x03. Each channel can be mapped to Limiter1 or Limiter2, or not mapped.

If a channel is not mapped, that channel will clip normally when 0 dB FS is exceeded. Each limiter will look at the present value of each channel that is mapped to it, select the maximum absolute value of all these channels, perform the limiting algorithm on that value, and then, if needed, adjust the gain of the mapped channels in unison.

The limiter attack thresholds are determined by the LxAT registers. When the Attack Threshold has been exceeded, the limiter, when active, automatically starts reducing the gain. The rate at which the gain is reduced when the attack threshold is exceeded is dependent upon the attack rate register setting for that limiter. A peak-detect algorithms used to control the gain reduction.

The release of limiter, when the gain is again increased, is dependent on an RMS-detect algorithm. The output of the volume limiter block is passed through an RMS filter. The output of this filter is compared with the release threshold, determined by the Release Threshold register.

When the RMS filter output falls below the release threshold, the gain is increased at a rate dependent upon the release rate register. The gain can never be increased past its set value and therefore the release will only occur if the limiter has already reduced the gain. The release threshold value can be used to set what is effectively a minimum dynamic range. This is helpful as over-limiting can reduce the dynamic range to virtually zero and cause program material to sound "lifeless".

In AC mode the attack and release thresholds are set relative to full-scale. In DRC mode the attack threshold is set relative to the maximum volume setting of the channels mapped to that limiter and the release threshold is set relative to the maximum volume setting plus the attack threshold.

8 User-programmable settings

8.1 EQ - biquad equation

The biquads use the equation that follows. This is shown in *Figure 51*.

$$Y[n] = 2(b0/2)X[n] + 2(b1/2)X[n-1] + b2X[n-2] - 2(a1/2)Y[n-1] - a2Y[n-2]$$
$$= b0X[n] + b1X[n-1] + b2X[n-2] - a1Y[n-1] - a2Y[n-2]$$

where Y[n] represents the output and X[n] represents the input. Signed, fractional 28-bit multipliers are used, with coefficient values in the range of 0x800000 (-1) to 0x7FFFFF (0.9999998808).

Coefficients stored in the user defined coefficient RAM are referenced in the following manner:

- CxHy0 = b1/2
- CxHy1 = b2
- CxHy2 = -a1/2
- CxHy3 = -a2
- CxHy4 = b0/2

The x represents the channel and the y the biquad number. For example C3H41 is the b0/2 coefficient in the fourth biquad for channel 3.

Figure 51. Biquad filter
8.2 Pre-scale

The pre-scale block, which precedes the first biquad, is used for attenuation when filters are designed that boost frequencies above 0 dBFS. The Pre-Scale block is a single 28-bit signed multiplier, with 0x800000 = -1 and 0x7FFFFF = 0.9999998808. By default, all pre-scale factors are set to 0x7FFFFF.

8.3 Post-scale

The STA323W provides one additional multiplication after the last interpolation stage and before the distortion compensation on each channel. The post-scale block is a 24-bit signed fractional multiplier. The scale factor for this multiplier is loaded into RAM using the same I²C registers as the biquad coefficients and the mix. All channels can use the same settings as channel 1 by setting the post-scale link bit.

8.4 Mix/bass management

The STA323W provides one post-EQ mixing block per channel. Each channel has two mixing coefficients, which are each 24-bit signed fractional multipliers, that correspond to the two channels of input to the mixing block. These coefficients are accessible via the User Controlled Coefficient RAM described below. The mix coefficients expressed as 24-bit signed, fractional numbers in the range +1.0 (8388607) to -1.0 (-8388608), are used to provide three channels of output from two channels of filtered input.

Figure 52. Mix/bass management block diagram
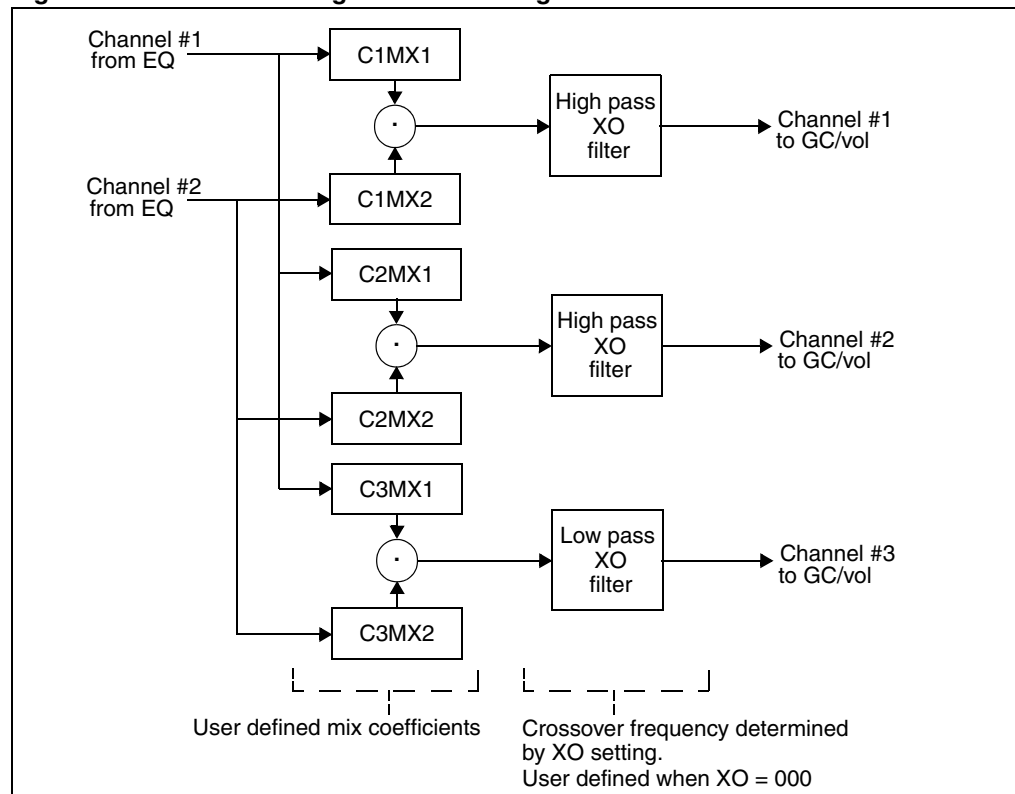

After mixing, STA323W also permits the implementation of crossover filters on all channels corresponding to 2.1 bass management operation. Channels 1 and 2 use a 1st order, high-pass filter and channel 3 uses a 2nd order low-pass filter corresponding to the setting of the XO bits of I2C register 0Ch. If XO = 000, user specified crossover filters are used.

By default these coefficients correspond to pass-through. However, the user can write these coefficients in a similar way as the EQ biquads. When user-defined setting is selected, the user can only write 2nd order crossover filters. This output is then passed on to the Volume and Limiter block.

8.5 Calculating 24-bit signed fractional numbers from a dB value

The pre-scale, mixing, and post-scale functions of the STA323W use 24-bit signed fractional multipliers to attenuate signals. These attenuations can also invert the phase and therefore range in value from -1 to +1.

It is possible to calculate the coefficient to use for a given negative dB value (attenuation) using the equations following.

- non-inverting phase numbers 0 to +1:
  - coefficient = round(8388607 * 10 ^ (dB/20))
- inverting phase numbers 0 to -1:
  - coefficient = 16777216 - round(8388607 * 10^(dB/20))

As can be seen by the preceding equations, the value for positive phase 0dB is 0x7FFFFF and the value for negative phase 0dB is 0x800000.

Coefficients for EQ, Mix and Scaling are handled internally in the STA323W via RAM. Access to this RAM is available to the user via an I^{2}C register interface. A collection of I^{2}C registers are dedicated to this function. The first register contains base address of the coefficient: five sets of three registers store the values of the 24-bit coefficients to be written or that were read, and one contains bits used to control the reading or writing of the coefficients to RAM. The following are instructions for reading and writing coefficients.

8.7 Reading a coefficient from RAM

1. Write 8-bits of address to I^{2}C register 0x16.
2. Write '1' to bit R1 (D2) of I^{2}C register 0x26.
3. Read top 8-bits of coefficient in I^{2}C address 0x17.
4. Read middle 8-bits of coefficient in I^{2}C address 0x18.
5. Read bottom 8-bits of coefficient in I^{2}C address 0x19.

8.8 Reading a set of coefficients from RAM

1. Write 8-bits of address to I^{2}C register 0x16.
2. Write '1' to bit RA (D3) of I^{2}C register 0x26.
3. Read top 8-bits of coefficient in I^{2}C address 0x17.
4. Read middle 8-bits of coefficient in I^{2}C address 0x18.
5. Read bottom 8-bits of coefficient in I^{2}C address 0x19.
6. Read top 8-bits of coefficient b2 in I^{2}C address 0x1A.
7. Read middle 8-bits of coefficient b2 in I^{2}C address 0x1B.
8. Read bottom 8-bits of coefficient b2 in I^{2}C address 0x1C.
9. Read top 8-bits of coefficient a1 in I^{2}C address 0x1D.
10. Read middle 8-bits of coefficient a1 in I^{2}C address 0x1E.
11. Read bottom 8-bits of coefficient a1 in I^{2}C address 0x1F.
12. Read top 8-bits of coefficient a2 in I^{2}C address 0x20.
13. Read middle 8-bits of coefficient a2 in I^{2}C address 0x21.
14. Read bottom 8-bits of coefficient a2 in I^{2}C address 0x22.
15. Read top 8-bits of coefficient b0 in I^{2}C address 0x23.
16. Read middle 8-bits of coefficient b0 in I^{2}C address 0x24.
17. Read bottom 8-bits of coefficient b0 in I^{2}C address 0x25.

8.9 Writing a single coefficient to RAM

1. Write 8-bits of address to I^{2}C register 0x16.
2. Write top 8-bits of coefficient in I^{2}C address 0x17.
3. Write middle 8-bits of coefficient in I^{2}C address 0x18.
4. Write bottom 8-bits of coefficient in I^{2}C address 0x19.
5. Write 1 to W1 bit in I^{2}C address 0x26.

8.10 Writing a set of coefficients to RAM

1. Write 8-bits of starting address to I^{2}C register 0x16.
2. Write top 8-bits of coefficient b1 in I^{2}C address 0x17.
3. Write middle 8-bits of coefficient b1 in I^{2}C address 0x18.
4. Write bottom 8-bits of coefficient b1 in I^{2}C address 0x19.
5. Write top 8-bits of coefficient b2 in I^{2}C address 0x1A.
6. Write middle 8-bits of coefficient b2 in I^{2}C address 0x1B.
7. Write bottom 8-bits of coefficient b2 in I^{2}C address 0x1C.
8. Write top 8-bits of coefficient a1 in I^{2}C address 0x1D.
9. Write middle 8-bits of coefficient a1 in I^{2}C address 0x1E.
10. Write bottom 8-bits of coefficient a1 in I^{2}C address 0x1F.
11. Write top 8-bits of coefficient a2 in I^{2}C address 0x20.
12. Write middle 8-bits of coefficient a2 in I^{2}C address 0x21.
13. Write bottom 8-bits of coefficient a2 in I^{2}C address 0x22.
14. Write top 8-bits of coefficient b0 in I^{2}C address 0x23.
15. Write middle 8-bits of coefficient b0 in I^{2}C address 0x24.
16. Write bottom 8-bits of coefficient b0 in I^{2}C address 0x25.
17. Write 1 to WA bit in I^{2}C address 0x26.

The mechanism for writing a set of coefficients to RAM provides a method of updating the five coefficients corresponding to a given biquad (filter) simultaneously to avoid possible unpleasant acoustic side-effects. When using this technique, the 8-bit address specifies the address of the biquad b1 coefficient (for example 0, 5, 10, 15, …, 45 decimal), and the STA323W generates the RAM addresses as an offsets from this base value to write the complete set of coefficient data.

Table 69.   RAM block for biquads, mixing, and scaling

Index (decimal)	Index (hex)		Coefficient	Default
0	0x00		C1H10 (b1/2)	0x000000
1	0x01		C1H11 (b2)	0x000000
2	0x02	Channel 1 – biquad 1	C1H12 (a1/2)	0x000000

63	0x3F	Unused		

8.11 Variable max power correction (address 0x27-0x28)

The MPCC bits determine the 16 MSBs of the MPC compensation coefficient. This coefficient is used in place of the default coefficient when MPCV = 1.

D7	D6	D5	D4	D3	D2	D1	D0
MPCC15	MPCC14	MPCC13	MPCC12	MPCC11	MPCC10	MPCC9	MPCC8
0	0	1	0	1	1	0	1
MPCC7	MPCC6	MPCC5	MPCC4	MPCC3	MPCC2	MPCC1	MPCC0
1	1	0	0	0	0	0	0

8.12 Fault detect recovery (address 0x2B - 0x2C)

FDRC bits specify the 16-bit fault detect recovery time delay. When FAULT is active, the TRISTATE output immediately goes low and is held low for the time period specified by this constant. A constant value of 0x0001 in this register is ~.083 ms. The default value of 0x000C specifies ~.1 mSec.

D7	D6	D5	D4	D3	D2	D1	D0
FRDC15	FDRC14	FDRC13	FDRC12	FDRC11	FDRC10	FDRC9	FDRC8
0	0	0	0	0	0	0	0

D7	D6	D5	D4	D3	D2	D1	D0
FDRC7	FDRC6	FDRC5	FDRC4	FDRC3	FDRC2	FDRC1	FDRC0
0	0	0	0	1	1	0	0

8.13 Status indicator register (address 0x2D)

D7	D6	D5	D4	D3	D2	D1	D0
PLULL						FAULT	TWARN
0						1	1

STATUS register bits serve the purpose of communicating the detected error or warning condition to the user. This is a read-only register and writing to this register would not be of any consequence.

8.13.1 Thermal warning indicator

Table 70. Thermal warning indicator

Bit	R/W	RST	Name	Description
0	R	1	RWRAN	0: thermal warning detected 1: normal operation (no thermal warning)

If the power stage thermal operating conditions are exceeded, the thermal warning indicator transmits a signal to the digital logic block to initiate a corrective procedure. This register bit is set to '0' to indicate a thermal warning and it reverts back to its default state as soon as the cause of the thermal warning has been corrected.

8.13.2 Fault detect indicator

Table 71. Fault detect indicator

Bit	R/W	RST	Name	Description
1	R	1	FAULT	0: fault issued from the power stage 1: normal operation (no fault)

As soon as the power stage issues a Fault error signal, thereby initiating the Fault recovery procedure described in *Section 8.12*, this register bit is set to '0' to indicate the error to the user. As soon as the fault condition (over-current or thermal) is corrected, this bit is reset back to its default state.

8.13.3 PLL unlock indicator

Table 72. PLL unlock indicator

Bit	R/W	RST	Name	Description
7	R	0	PLLUL	0: normal operation (PLL is in a locked state) 1: PLL unlock is detected (due to probable clock loss)

Under normal conditions (with the correct clock) the PLL is locked into an internal clocking frequency. However, if the clock is insufficient or if it is abruptly lost, the PLL lock state is lost and this information is relayed to the user via setting the PLLUL bit of the Status register to '1'. As soon as the PLL reverts back to a locked state, this bit is set to '0'.

OUTLINE AND MECHANICAL DATA

PowerSO-36

0096119 C

In order to meet environmental requirements, ST offers these devices in ECOPACK® packages. These packages have a Lead-free second level interconnect . The category of second level interconnect is marked on the package and on the inner box label, in compliance with JEDEC Standard JESD97. The maximum ratings related to soldering conditions are also marked on the inner box label. ECOPACK is an ST trademark. ECOPACK specifications are available at: www.st.com.

9   Revision history

Table 73.   Document revision history

Date	Revision	Changes
15-Nov-2006	5.0	Update into latest template.
08-Jun-2006	4.0	Added new chapters. Updated *4: Electrical characteristics curves*. Modified the minimum value of Vcc paramter.
02-Feb-2006	3.0	Modified the ordering part numbers.
02-Jan-2006	2.0	Modified page 12/41: Configuration Register A (Address 00h)
01-Jul-2005	1.0	Initial release

Please Read Carefully:

Information in this document is provided solely in connection with ST products. STMicroelectronics NV and its subsidiaries ("ST") reserve the right to make changes, corrections, modifications or improvements, to this document, and the products and services described herein at any time, without notice.

All ST products are sold pursuant to ST's terms and conditions of sale.

Purchasers are solely responsible for the choice, selection and use of the ST products and services described herein, and ST assumes no liability whatsoever relating to the choice, selection or use of the ST products and services described herein.
